#### Abstract

This paper pronounces a modified numerical scheme to the conventional formula of Newton-Raphson for solving the nonlinear and transcendental equations especially those which cannot be solved by the basic algebra. Finding the derivative of a function is difficult in some case of problems. The present formula is made with the target to aloof the need of obtaining the derivative of the function. Comparative analysis shows that the present method is faster than Newton-Raphson method, Adomian method, Rabolian method, Abbasbandy method, Basto method \& Feng method. Iteration cost effective parameters - number of iteration steps \& the value of effective error is also found to be minimum than these methods.

Keywords: Algebraic \& Transcendental equations, Bisection method, Regula-Falsi method, Newton-Raphson method, Iteration Process, Derivative free methods.

## 1. Introduction

TThe laws of basic mathematics are unable to solve many equations of the form $f(x)=0$ which contain the partial or full involvement of the terms containing non-linear algebraic functions particularly of higher order and having transcendental terms. Numerical analysis is a branch of mathematics which is generally used to solve those algebraic and transcendental equations, which are difficult to solve by usual Mathematical methods. Methods like Bisection, Regula falsi and Newton-Raphson are oftenly used for this purpose. The various methods are discussed below.

Maheshwari, A. K.

1. $x_{i}$ and $x_{m(i, i+l)}$
2. $x_{i+1}$ and $x_{m(i, i+1)}$

Thus, there can be two cases

$$
f\left(x_{i}\right) f\left(x_{m(i, i+1)}\right)= \begin{cases}<0 & \text { i.e. the product is negative }  \tag{1.1}\\ >0 & \text { i.e. the product is positive } \quad \text { For } i=1 \text { or } 2\end{cases}
$$

In the first case we say the actual root lies between $x_{i}$ and $x_{m(i, i+l)}$ where as the second case escapes the root to be within $x_{i}$ and $x_{m(i, i+l)}$ and fall it in the next interval. This strategy can be used to further refine the result to its actual convergence at last.

### 1.2 Regula-Falsi Method

This method is based on the strategy of assumption in bisection method and hence considered as the improvement of above method. Here, the process algorithm involve the following modified formula for $x_{m(i, i,+1)}$

$$
\begin{equation*}
x_{m(i, i+1)}=x_{i}-\frac{f\left(x_{i}\right)\left(x_{i+1}-x_{i}\right)}{f\left(x_{i+1}\right)-f\left(x_{i}\right)} \tag{1.2}
\end{equation*}
$$

Bracketing of roots is made exactly in the same way as bisection method.

### 1.3 Newton-Raphson Method

Both the above methods require the consideration of two initial points in each proceeding step. This method is advancement to both the methods and requires the input of a single point. Besides, here the result obtained in one step serve the input point for the next step and there is no need to check the property of obtained root each time. The formula defining its equation is as follows,

$$
\begin{equation*}
x_{i+1}=x_{i}-\frac{f\left(x_{i}\right)}{f^{\prime}\left(x_{i}\right)} \tag{1.3}
\end{equation*}
$$

This method requires the computation of one derivative but its convergence is far better than Bisection and Regula falsi method. For this reason, NewtonRaphson is considered as the best among the three methods.

Many times it is quite difficult to obtain the derivative of a function due to its complicated nature. In those cases, the situation deprives to use the NewtonRaphson method which is considered to be best among the conventional methods. The present formula is made with the target to obtain the result of the targeted problems in all such situations. Comparative analysis shows that the present
method is faster than many methods of its class i.e. Newton-Raphson method, Adomian method, Rabolian method, Abbasbandy method, Basto method \& Feng method. Iteration cost effective parameters - number of iteration steps \& the value of effective error is also found to be minimum than these methods.

## 2. Formula Derivation

Let, us assuming the function defining the equation $f(X)=0$ is continuous and differentiable in the whole domain and at least in the part of domain in which the real root of the equation lies. The present iteration result runs through the basic strategies of Newton-Raphson method. So, assuming two points $\left(X_{n 0}, f\left(X_{n 0}\right)\right)$ and $\left(X_{n p}, f\left(X_{n 1}\right)\right)$ such that $f\left(X_{n 0}\right)$ and $f\left(X_{n 1}\right)$ are opposite in sign and the ordinate part of the given equation $f(X)=0$ follows the inequality $\left|f\left(X_{n 0}\right)\right|<\left|f\left(X_{n I}\right)\right|$. In this way, from the Taylor's expansion of $f(X)$ about the point " $X_{n 0}$ " we have

$$
\begin{equation*}
f(x)=f\left(x_{n 0}\right)+\frac{X-X_{n 0}}{1!} f^{\prime}\left(X_{n 0}\right)+\frac{\left(X-X_{n 0}\right)^{2}}{2!} f^{n}\left(x_{n 0}\right)+\ldots \ldots \ldots \tag{2.1}
\end{equation*}
$$

Where, $X_{n 0}$ is the initial approximation to the root of the equation $f(X)=0$.
Let's approximate $f^{\prime}\left(X_{n 0}\right)$ as $\frac{f\left(X_{n}\right)_{\text {Re gula-falsi }}-f\left(X_{n}\right)_{B i \text { section }}}{\left(X_{n}\right)_{\text {Re gula-flali }}-\left(X_{n}\right)_{\text {Bisection }}}$ and say it $f(z)$ for convenience. Further, if $X_{n}$ constitutes a root of the equation $f(X)=0$ in the open interval I, in which the function is continuous and has well defined first order derivative. Then,

$$
\begin{equation*}
f\left(X_{n}\right)=f\left(X_{n 0}\right)+\frac{\left(X_{n}-X_{n 0}\right)}{1!} f(z)+\frac{\left(X_{n}-X_{n 0}\right)^{2}}{2!} D(f(z))+\ldots \ldots . \tag{2.2}
\end{equation*}
$$

Using the fact $f\left(X_{n}\right)=0$ equation (2.2) becomes
$0=f\left(X_{n 0}\right)+\frac{\left(X_{n}-X_{n 0}\right)}{1!} f(z)+\frac{\left(X_{n}-X_{n 0}\right)^{2}}{2!} D(f(z))+\ldots \ldots .$.
Considering only the linear terms of equation (2.3), the value of the root $X_{n}$ can be obtained,

$$
\begin{equation*}
X_{n}=\frac{X_{n 0} f(z)-f\left(X_{n 0}\right)}{f(z)} \tag{2.4}
\end{equation*}
$$

## 3. Process Algorithm

i) Choose any two points say $X_{0}$ and $X_{1}$ such that $\mathrm{f}\left(X_{0}\right)$ and $\mathrm{f}\left(X_{1}\right)$ are opposite in sign. The ordinate with lesser $f(X)$ is assigned $X_{n 0}$ and the second to be $X_{n 1}$.

Maheshwari, A. K. ii) Find the results by Bisection method (equation (1.1)), Regula Falsi method (equation (1.2)) and present formula (equation (2.4)) for the two points $X_{n 0}$ and $X_{n 1}$.
iii) The Following iterations were made by taking $X_{n 0}$ as the result of present formula, $X_{n 1}$ as the Result of Regula Falsi formula through redefining $f(z)$ as $=\frac{f\left(X_{n 0}\right)-f\left(X_{n 1}\right)}{\left(X_{n 0}\right)-\left(X_{n 1}\right)}$.
iv) The process is repeated to get the result from next iteration step which in turn will give more exact result.
v) The process terminates when required level of accuracy is obtained.

## 4. Numerical Results and Discussions

Following illustrative example defines the result obtained by present method to solve targeting type of equations. At the same time, the results are compared with some other recent methods to compare the efficiency and accuracy of it.
Illustrative problem 1: Consider the following equation

$$
\begin{equation*}
f(x)=x^{2}-(1-x)^{5}=0 \tag{8}
\end{equation*}
$$

Taking $x_{0}=0.2$ as the initial approximation. The results obtained by NewtonRaphson method, Adomian method, Rabolian method, Abbasbandy method, Basto method, Feng method and the present method is shown in Table 1

Table-1: Comparison of the results of $f(x)=x^{2}-(1-x)^{5}=0$ with different methods

| Method | Number of Iterations | $\boldsymbol{X}_{n}$ | $f\left(\boldsymbol{X}_{n}\right)$ |
| :--- | :---: | :---: | :--- |
| Newton-Raphson | 03 | 0.345953774 | $-1.7 \mathrm{E}-06$ |
| Adomian | 10 | 0.340622225 | -0.00862 |
| Rabolian | 05 | 0.346021366 | 0.000107 |
| Abbasbandy | 02 | 0.345954646 | $-2.7 \mathrm{E}-07$ |
| Basto | 02 | 0.345952219 | $-4.2 \mathrm{E}-06$ |
| Feng | 03 | 0.345954816 | $-7.8 \mathrm{E}-11$ |
| Present | 04 | 0.345954816 | 0 |

Illustrative problem 2: Consider again the equation

$$
\begin{equation*}
f(x)=e^{x}-3 x^{2}=0 \tag{9}
\end{equation*}
$$

Taking $\mathrm{x}_{0}=0$ as the initial approximation. Various results of different methods and the present method are shown in Table 2.

Table-2: Comparison of the results of $f(x)=e^{x}-3 x^{2}=0$ at $\mathrm{x}_{0}=0$ with different methods

| Method | Number of Iterations | $\boldsymbol{X}_{\boldsymbol{n}}$ | $\boldsymbol{f}\left(\boldsymbol{X}_{\boldsymbol{n}}\right)$ |
| :--- | :---: | :---: | :---: |
| Newton-Raphson | 05 | -0.458962274 | $-2.2 \mathrm{E}-08$ |
| Abbasbandy | 05 | -0.458964191 | $-6.5 \mathrm{E}-06$ |
| Basto | 02 | -0.458992962 | -0.0001 |
| Feng | 05 | -0.458962268 | $1.25 \mathrm{E}-10$ |
| Present | 04 | -0.458962268 | $-2.9 \mathrm{E}-11$ |

Illustrative problem 3: Consider again the equation

$$
\begin{equation*}
f(x)=e^{x}-3 x^{2}=0 \tag{9}
\end{equation*}
$$

Taking $\mathrm{x}_{0}=0.5$ as the initial approximation. Various results of different methods and the present method are shown in Table 3.

Table-3: Comparison of the results of $f(x)=\mathrm{e}^{x}-3 \mathrm{x}^{2}=0$ at $\mathrm{x}_{0}=0.5$ with different methods

| Method | Number of Iterations | $\boldsymbol{X}_{\boldsymbol{n}}$ | $\boldsymbol{f}\left(\boldsymbol{X}_{\boldsymbol{n}}\right)$ |
| :--- | :---: | :---: | :---: |
| Newton-Raphson | 04 | 0.910007662 | $-2.7 \mathrm{E}-07$ |
| Abbasbandy | 04 | 0.910007573 | $-1.5 \mathrm{E}-09$ |
| Basto | 03 | 0.910007573 | $-1.5 \mathrm{E}-09$ |
| Feng | 04 | 0.910007573 | $-6.3 \mathrm{E}-10$ |
| Present | 04 | 0.910007572 | $-2.4 \mathrm{E}-12$ |

Illustrative problem 4: Consider the following equation

$$
\begin{equation*}
f(x)=\sin x=0 \tag{10}
\end{equation*}
$$

Maheshwari, A. K. The results obtained by Newton iteration, Hybrid iteration, Modified Newton method of Nasr-Al-Din Ide, Maheshwari's method and present iteration method are shown in Tables 4-8.

Different results for the equations of the form $f(x)=0$ are shown in Table 1-8. Here, $x_{0}$ represents the initial approximation of the root of the equation $f(x)=0, n$ is the iteration number made to obtain the final result $x_{n}$ and $f\left(x_{n}\right)$ represents the value of error at the $\mathrm{n}^{\text {th }}$ iteration step w.r.t. its targeted value " 0 ". It is apparent from these results that the present iterative formula is more effective than the other formulas of its class and gives the least value of working error. For instance, in illustrative problem-1, the present method gives $f\left(x_{n}\right)=0$ in the $4^{\text {th }}$ iteration step which clears that the solution obtained in this step is exact. Whereas, the other methods for the same example contains some error. Similarly, Table $2 \& 3$ for the other two examples shows the least value of error by the present method. Table 4-8 for the illustrative problem-2 also presents the stepwise results. The various results clears that the present method gives the least error as clear by the last columns under $\left|f\left(x_{n}\right)\right|$. This again proves the efficiency of the present method.

## Maheshwari, A. K. 5. Conclusion

Various observations can be made from the result drawn in the Tables. The main conclusions are as follows:
I. Present method is a derivative free method that takes lesser number of iterations to obtain the required accuracy.
II. Various results in the last column of the Tables show the deviation in $f(x)$. Here, it can be concluded that the value of error is least in case of the present method.
